**ABSTRACT**

A study on the hepatoprotective effects of methanol extract of *Spinacia oleracea* (MESO) against carbon tetrachloride induced hepatotoxicity in rats (150 to 180g) was done. Thirty male albino rats of wistar strain were divided into 5 groups with six individual each. The group-I served as normal control, group II as negative control intoxicated with carbon tetrachloride (1.9 ml/kg, Intra Peritoneal), groups III, IV & V with carbon tetrachloride and methanol extract of *Spinacia oleracea* at 100µgm/ml, 200µgm/ml & 300µgm/ml per os, respectively, for 14 days. At the end, the animals were sacrificed, blood samples were collected and analysed. The results showed carbon tetrachloride administration was associated with considerable increase in the activities of Alanine amino transferase, Aspartate amino transferase and Bilirubin (P<0.05) in comparison with the respective mean values of the control. The antioxidants such as, serum catalase, reduced glutathione, glutathione peroxidase, vitamin E, vitamin C & superoxide dismutase, blood parameters such as total WBC, RBC, Hb, and Haematocrit were observed to be lower than the control. The hepatic chord architecture was disturbed. Upon treatment with MESO the antioxidant enzymes and blood parameters were restored to significantly near normal level. This research work showed that MESO was successful at 300µgm/ml, in counteracting carbon tetrachloride induced Hepatotoxicity and hepatic architecture remediation to significantly near normal level. It may also be inferred that, the level of progressive amelioration may be due to the total phenolics, flavonoids and other antioxidants composition in the *Spinacia oleracea* extract.

**Keywords:** Antioxidants, Alanine amino transferases, Aspartate transaminases, Glutathione, Hepatotoxicity, Haematocrit.
1. INTRODUCTION
Plants have been investigated for their medicinal properties throughout the world, mainly due to their potent pharmacological activities, low toxicity and economic viability. In the last decade the hunt for naturally occurring antioxidants has grown tremendously since free radicals are known to quench various ailments that affect human health. Consumption of herbal antioxidants improves health. This necessitates the search for natural plant products which could effectively intervene in the onset and morbidity of the disorders and diseases. It was well reported that expression of many disorders or ailments / diseases is associated with the generation of reactive oxygen species (ROS) or free radicals. The liver is the largest exocrine gland in our body. It is the vital organ undertaking wide range of functions, such as detoxification, Protein – Fat – Carbohydrate metabolism, storage of iron and vitamins. The liver also plays major role in decomposition of RBCs, hormone production, plasma protein synthesis, glycogen storage and synthesis of urea. The organ liver is inevitable for survival and one cannot live without it for long period. The liver acts as the chief site for intense metabolism and excretion. The liver is the key organ of metabolism and detoxification. Regular exposure to a variety of abusive measures adds on to hepatic injury. During liver injury, the liver marker enzymes like Alanine amino transaminase (ALT), Aspartate aminotranserase (AST), Bilirubin are present in blood serum in very low concentration and thus provide us indications on hepatic health. Liver diseases were among the first disorders to which serums test were applied and have proved to be useful in diagnostic purposes. Free radicals or Reactive oxygen species (ROS) are often produced as byproducts of biological reactions or as a result of intake of exogenous elements which foster oxidative damage, leading to a wide range of biological malfunctions prompting DNA damage, carcinoma, cardiovascular, metabolic and neuro degenerative disorders, as well as acceleration of senescence.

Carbon tetrachloride (CCl₄) is one of the most potent hepatotoxins and is widely used in scientific research to evaluate hepatoprotective agents. The hepatotoxic effect of CCl₄ is largely due to its active metabolite, trichloromethyl free radical (CCl₃⁻ and / or CCl₃OO⁻) by chronic or acute vehicles. The CCl₄ is shown to induce hepatocellular carcinomas in rodents by oral, inhalation, and parenteral (Intraperitoneal) exposure.

High consumption of fruits and vegetables is associated with low risk for these diseases, which is attributed to the antioxidant vitamins and other phytochemicals. Spices and herbs are recognized as sources of natural antioxidants and thus play an important role in the chemoprevention of diseases and aging. The phytochemicals tests indicated the presence of alkaloids, glycosides, tannins, and flavonoids in the crude methanolic extract of plants. Several of such compounds are known to possess potent antioxidant activity. Phenolic compounds are commonly found in both edible and other traditional medicinal plants, and they have been reported to have multiple biological activities, including free radical scavenging activity.

The spinach leaves, (Spinacia oleracea L.), a flowering plant of family ‘Chinopodiaceae’, is widely available commonly consumed vegetable, recognized as ‘palak’ in vernacular. It is reported
to have phyto-nutrients such as Carotene-β, Crypto-xanthin-β, Lutein-zeaxanthin, Vitamins such as, Folic acid, Niacin, Pantothenic acid, pyridoxine, Riboflavin, Thiamin, Vitamin-A, Vitamin-C, Vitamin-E and Vitamin-K, Electrolytes such as Sodium, Potassium, minerals such as, Ca, Cu, Fe, Mg, Mn and Zn. As per many investigations on the activity of spinach parts such as leaves, seeds in vivo, the present research study was aimed at an evaluation of methanolic extract of Spinacia oleracea (MESO) and its anti-oxidants in ameliorating the induced hepatotoxicity to CCl₄ exposure and circulating liver marker enzyme levels and proteins using wistar albino rat models.

2. MATERIALS AND METHODS

2.1 Chemicals and reagents

The Anthrone Reagent, Folin-Ciocalteau Reagent, Ninhydrin, thiobarbituric acid (TBA), the carbon tetrachloride (CCl₄), 3-(4,5-dimethyl thiazol-2yl)-2,5-diphenyl tetrazolium bromide (MTT), 2,2-diphenyl-1picrylhydrazyl (DPPH), and 5,5’-dithiobis-2-nitrobenzoic acid (DTNB), Methanol, 2,4- dinitrophenyl hydrazine-thiourea-CuSO₄ reagent, and isobutyl alcohol were procured from Sigma-Aldrich Chemicals (Bangalore). Remaining analytical grade chemicals and estimation kits were purchased from commercial sources and used.

2.2 Plant Material

The spinach leaves (Spinacia oleracea L.) were purchased from a local market, Vellore, Tamil Nadu, India and the plants were authenticated by the Botany Department, Govt. Arts and Science College, Thiruvannamalai (Thiruvalluvar University), Tamil Nadu, India. The plant materials were washed in tap water, shade dried and powdered.

2.3 Experimental animals

The experimental animals used for the study were male Wistar rats Rattus norvegicus, weighing (160–180 g) and procured from Kings Institute of Preventive Medicine, Guindy, Chennai, and fed with standard rat chow (Amrut Laboratory Animal Feed, Bangalore, India) and water ad libitum. Forty eight animals were used for the experiment and maintained as per the Committee for the purpose of control and supervision of Experiments on Animals (CPCSEA) guidelines. Animals were acclimatized for one week prior to experiment. The animals were maintained under standard laboratory conditions of temperature (25 ± 2%) and humidity (55 ± 5%) with 12 h light-dark cycle.

2.4 Extraction and fractionation

The powdered leaves material (800 g) was successively extracted with 95% methanol using soxhlet extractor. The marc left after the methanol extraction was macerated with distilled water for 24 h. The solvents were distilled off under reduced pressure below 45°C to afford Spinacia oleracea a methanol extract (MESO, 12.4% w/w).

2.5 Preliminary photochemical screening

Preliminary phytochemicals analysis was performed as per standard methods in order to identify the nature of phyto-constituents in the methanol extract of spinach leaves (Spinacia oleracea L.)

2.6 Antioxidant enzymes assay (DPPH scavenging assay)

The in vitro free radical scavengical activity of methanol extract of Spinacia oleracea (MESO) was measured by 2, 2-diphenyl-1-picrylhydrazyl (DPPH). Various concentrations of the extract (0.8, 4, 20 and 100 µg/ml) were added to a solution of 1.5 x 10-4m DPPH (sigma, Bangalore) in methanol and the reaction mixture was shaken vigorously. Quercetin, a known antioxidant was
used as normal control. The amount of DPPH remaining was determined at 520nm and the radical scavenging activity was obtained from the equation.

Radical Scavenging activity (%) = 
\[ \frac{OD \text{ Control} - OD \text{ Sample}}{OD \text{ Control}} \times 100 \]

2.7 Determination of total phenolics and flavonoids content

In studying phenolics antioxidants, the total phenolics and flavonoids content of plant extracts were determined as per Folin-Ciocalteau assay method \(^1\). The total phenolics content was expressed as milligrams of Gallic acid equivalents/g extract (mg GAE/g of dry mass) and the total flavonoids content was expressed in milligrams of quercetin equivalents/g of extract (mg QE/g of dry mass).

2.8 Determination of LD\(_{50}\) of CCl\(_4\) for Male wistar rats

The acute oral toxicity studies of Spinacia oleracea extract was carried out as per OECD guidelines. The rats were orally fed with different doses of CCl\(_4\) and the LD\(_{50}\) value was calculated as per the method of OECD – 423 guidelines and was found to be 2400ml/kg body weight for a period of 14 days (OECD – 423, 2001). The rats were treated with 1.9ml/kg of CCl\(_4\) daily intra-peritoneal (IP) to induce hepatotoxicity \(^15\). The rats were maintained in the above condition for 14 days and on the 15th day, the rats were anesthetized and sacrificed. Then the blood and liver samples were collected, processed, analysed for various biochemical factors and antioxidant enzymes in the blood samples and they were duly reported.

2.10 Blood sampling assay and liver marker enzymes

The whole blood samples were collected into heparinized capillary tubes, filled up to 2/3 of the tube, sealed and centrifuged at 10,000rpm in a haematocrit centrifuge for 10 minutes and analyzed for the erythrocytes count, leucocytes count and packed cell volume (PCV %) also known as Hematocrit (HCT) \(^16\). Packed cell volume was determined using a haematocrit reader and PCV was expressed as percentage erythrocytes blood contained and the haemoglobin concentration was estimated as per using the formula

\[ \text{Hb concentration} = \frac{1}{3} \times \text{PCV concentration} \]

Liver marker enzymes such as Alanine transaminase (ALT), Aspartate aminotrasferase (AST) and Bilirubin levels were determined in serum proteins as per standard methods. However, the level of tissue toxicity is tested as Level of lipid peroxidation (LPO) and expressed in terms of GPx, (Glutathione peroxidase), Glutathione (GSH), Superoxide dismutase (SOD) and catalase (CAT) \(^16\). They were determined by the standard methods to assess oxidative stress, on the ‘in vivo’ subjects.

2.11 Histopathological Examination

For the histopathological observations at the light microscopic level, fresh tissue pieces of liver were fixed in Bouin’s fluid \(^17\). Following two days of
fixation, the specimens were washed and dehydrated through an ascending series of ethanol (70 – 100%). Then, they were cleaned with xylene and embedded in paraffin wax, then sectioned at 5μm thickness using a rotary microtome. Sections were rehydrated in distilled water and stained with Hematoxylin-Eosin (H&E) and then examined under light microscopy.

2.12 Statistical analysis
The results were expressed as mean ± SE of six individuals and analyzed by one-way analysis of variance (ANOVA) 18. The SPSS software Version 22 was also used to analyse the obtained data. Post hoc - SNK test was done for variation analysis in addition to student t-test for comparative study; the significantly different value was considered at p<0.05, with normal control. However, p<0.001 was considered to be significantly lower with normal control.

3. RESULTS AND DISCUSSIONS
3.1 Preliminary phytochemicals screening
Screening plant extracts for their antioxidant potency in order to identify their ability in scavenging free radicals (ROS) and binding with metal ions of oxidative reactions is considered as an important step prior to the isolation of antioxidant phytochemicals 19.
In the preliminary phytochemicals analysis, methanol extract of Spinacia oleracea (MESO) showed the presence of various phytoconstituents as listed in Table 1. It was observed that, carbohydrate, protein, fat and total amino acid content is moderately high. The carbohydrates were 40.5g/100g, protein was 18.4g/100g, fat was 1.20g/100g and total amino acid content was (12.5g/100g), indicating the phytoconstituents are moderately available in spinach leaves.
The Vitamins and Minerals Factors of the leafy parts of the plant Spinacia oleracea are presented in Table-2. All the non – enzymatic antioxidants such as total phenolics, β- carotene, ascorbic acid, thiamine, flavonoids etc., were found in high content. The β- carotene level was at 30.2 μg/100g, ascorbic acid (vitamin C) is measured to be at 355mg/100g, thiamine at 0.21 μg/100g, total ash at 4.2g/100g, potassium at 412 mg/100g, sodium at 511mg/100gm, Iron at 9.7mg/100g, and calcium at 345mg/100g.

3.2 Effect of MESO on the Antioxidant Activity (DPPH assay)
The DPPH assay is the widely used as screening method for antioxidant activity of plant extracts 19. DPPH is relatively stable, nitrogen-centered free radical which produces violet colour in ethanol solution. It will be reduced to a yellow coloured product, diphenylpicryl hydrazine, with the addition of the plant extracts in a concentration dependent manner. The reduction in the number of DPPH molecules can be correlated with the number of available hydroxyl groups. The Detoxification of excess Reactive Oxygen Species (ROS) produced during stress is important as it may induce membrane lipid peroxidation, enzyme inhibition and nucleic acid damage 20.
Table-3 shows the antioxidant properties which include the (1, 1-diphenyl-2- picrylhydrazyl) DPPH assay, the antioxidant enzymes such as catalase and superoxide dismutase (SOD) and the non enzymatic antioxidant glutathione. The DPPH assay shows that MESO has a 69% antioxidant activity. Similarly the other antioxidant enzymes such as SOD, GSH and Catalase showed decent levels of content [MESO = SOD - 225µgm/ minute/ mg protein; the catalase activity was 64.2µmol/min/g; and Glutathione of MESO was 79mg/g;] the extract showed significant inhibition percentage (stronger hydrogen donating ability).
and may be positively correlated with total phenolics content (TPC)\textsuperscript{21}. The phytochemicals analysis showed the presence of total phenolics content (TPC) as 32.15mg GAE/g and total flavonoids content (TFC) as 18.3QE/g in \textit{MESO}. The amount of total phenolics was determined with the Folin-Ciocalteau reagent. Gallic acid was used as a standard compound. The total phenols were expressed as mg/g Gallic acid equivalent (GAE). The maximum flavonoids content in the metholic extracts of \textit{Spinacia oleracea} was determined with the Quercetin reagent. Quercetin was used as a standard compound and the total flavonoids were expressed as mg/g Quercetin equivalent\textsuperscript{22}.

\subsection*{3.3 Effect of MESO on the liver function analysis}
Administration of CCl\textsubscript{4} for 14 days caused the level of ALT to get raised at 101 ±1.11 IU/L which was considerably reduced to 40 ±1.01 IU/L by the administration of MESO, at 300μgm/ml which is close to control value of 39.5 ±1.11 IU/L. (Table-4). Similarly the level of AST was elevated to 1288±1.02 (IU/L) by CCl\textsubscript{4} (Group-II), was effectively reduced to 345 ±1.02 IU/L by MESO, at 300μgm/ml; thus reducing the AST level to near normal value close to the control 359.5 ±1.01 IU/L (Group-I). The elevated Bilirubin level of 0.94 ±1.01mg/dL due to CCl\textsubscript{4} toxicity was reportedly reduced by MESO at 300μgm/mL, to 0.49±1.02mg/dL which was almost close to the normal control value of 0.48 ±1.01mg/dL. The ALT and the Bilirubin levels were reported to be significantly higher (p<0.05) Vs normal control at MESO of 300μgm/ml. However, the AST level at 300μgm/ml of MESO was significantly lower (p<0.05) Vs negative control.

\subsection*{3.4 Effect of MESO on the level of non-enzymatic}
The level of non-enzymatic antioxidants (GPx, GSH, SOD, CAT, Vit.C and Vit.E respectively) as observed in CCl\textsubscript{4} control group rats (Table-5), were significantly (p<0.05) low, indicating the rise of ROS group and significant damage to the antioxidant system. However, the MESO treated groups, recorded with rising values close to the normal control levels, indicating remarkable antioxidant effect. Inactivation, detoxification, removal of ROS and other free radicals depend on enzymatic and non-enzymatic antioxidants. The important enzymatic antioxidants in the tissues are SOD, CAT, glutathione peroxidase (GPx), Vit. C and Vit. E. These antioxidants together with GSH act to prevent the formation of free radicals and thereby prevent oxidative stress\textsuperscript{23}.

Upon exposure to methanol extract of \textit{Spinacia oleracea} (MESO), in this study, they have got improved to near normal levels as shown by the control. (The values at 300μgm/ml are given as per below;) the GPx of MESO was 5.31±1.05, against CCl\textsubscript{4} impacted value of 2.08±1.02μgm/ml; and the values were close to the control value of 5.71±1.02 μgm/ml. The GSH of MESO = 4.38±1.01mg/mg, against CCl\textsubscript{4} =1.42±1.05mg/mg; and the value was near the normal value of 4.55±0.11mg/mg; The value for SOD of MESO was 7.42±1.01u/min/mg, as against CCl\textsubscript{4} exposed rats level of 4.1±1.01u/min/mg; whereas the value of control was 7.88±1.05μgm/ml; and the Catalase (CAT) levels of MESO at 82.7±1.01 u/min/mg, as against CCl\textsubscript{4} exposed rats level of 42±1.04 u/min/mg liver protein and the value of the control group was 90.5±1.05 u/min/mg. The ascorbic acid of the CCl\textsubscript{4} diseased is measured to be 1.15±1.01mmol/mg tissue, which has got improved to 1.52±1.03mmol/mg tissue as against
control rats value of 1.63±1.01 mmol/mg tissue. The vitamin E content of CCl₄ intoxicated rats was measured at 0.52±1.02 mmol/mg tissue, whereas the control group was measured at 1.24±1.01 mmol/mg and the effect of **MESO** at 300μgm/ml was 1.02±1.11 mmol/mg, which is obviously a significant recovery.

Reduction in the enzyme activities towards the respective normal values by **MESO** at different dose levels (100, 200 and 300 mg/kg) is an indication of stabilization of plasma membranes and repair of liver tissue damage. The first line of defence against ROS is displayed by the antioxidant enzymes, such as SOD and CAT. The GSH, a non-enzymatic antioxidant, plays a pivotal role in protecting organ against toxicity. These antioxidants mainly convert active oxygen molecules into non-toxic compounds. It was observed that, Glutathione peroxidase (Gpx), Glutathione (GSH), Superoxide dismutase (SOD) and Catalase (CAT) levels of liver protein were low in the CCl₄ diseased rats. And it may be due to the accumulation of superoxide radicals and hydrogen peroxide.

### 3.5 Effect of **MESO** on the blood parameters

As summarized in Table-6, injection of CCl₄ in rats with significant (P≤0.05) reduction of WBC, RBCs counts, Hb content as compared with control. Oral administration of **MESO** for 14 days along with CCl₄ ameliorated the suppressive effect of CCl₄ in group III, IV and V at 300μgm/ml when compared with 100μgm/ml and 200μgm/ml. The amelioration by **MESO** is reported to the near normal values that were exhibited in control group. The WBC count of 12.2 thousand in a unit blood was raised to the level of 21.5 thousands which was very close to the level of control (group-I) at 22.1 thousands per unit. Similarly the RBC count is raised from 5.7 millions to 8.5 million which is close to the control values of 8.7 million per unit blood. The hemoglobin content in group-V was raised to 13.5 g/dL from 8.2 g/dL of CCl₄ group-II which was close to 14.2 g/dL the value of the control. The hematocrit value too have improved in group-V (44.9%) when compared with group-II (30%) which is near normal value of 47% in group-I.

### 3.6 Histopathological findings

The oral administration of methanol extract of *Spinacia oleracea* (*per os*) for 14 days in addition to 1.9ml of CCl₄ through intraperitoneal (IP) route did offer remarkable hepatic remediation at 300μgm/ml level and restored the hepatic architecture close to the normal control group of rats.

**Figure 1** showed (normal control, untreated normal liver) the composition of hexagonal or pentagonal lobules with central veins and peripheral hepatic triads or tetrads embedded in connective tissue; Hepatocytes were regular and contain a large spheroidal nucleus with a distinctly marked nucleolus and peripheral chromatin distribution. (figures at a resolution of ×300).

However, the CCl₄ exposed negative control group (**Figure 2**) revealed that, there was dilation of blood sinusoids, single cell necrosis which affected most of the cell cords. But in **Figure 3(c)**, the restoration of hepatocytes, close to normal arrangement, at 300μgm/ml of **MESO** although cytoplasmic vacuoles were observed. **Figure 3(a) & (b)** show the hepatic architecture at 100 and 200 μgm/ml of **MESO**, respectively, where, there is no response in the mentioned concentrations.

But, it was evidenced that the 300μgm/ml of **MESO** was efficient enough in regenerating the affected hepatic cells from their organization and also showed the dilated blood sinusoids and
cytoplasmic vacuoles. The above results support the view on stabilization of plasma membranes of hepatocytes and thus reduced ROS levels by the activity of MESO. Previous phytochemicals investigations on Spinacia oleracea reported the presence of flavonoids and phenolics. The antioxidant activity, flavonoids and phenolics may be responsible for hepatoprotective activity.

4. DISCUSSIONS

The screening for ‘biochemical factors’ in the methanol extract of Spinacia oleracea (MESO) showed that fairly higher content of carbohydrates, proteins, total amino acids, fats, mono unsaturated fatty acids, polyunsaturated fatty acids, prolines and negligible amount of glycosides were present. These were reported to improve higher hepatoglycogen level between carbohydrate metabolism and antioxidant systems. Amino acids can directly scavenge super oxide, hydroxyl radicals and singlet oxygen and reduce H₂O₂ to water via ascorbate peroxidase reaction. Amino acids regenerate tocopherol from tocopheroxyl radical providing membrane protection and also carries out a number of non-antioxidant functions in the cell. The dietary fats that are present in the vegetable oils and animal based diet can influence the extent of the formation of lipid radicals and hence lipid peroxidation products, which may be in accordance to the oxidative injury. These injuries may cause changes in the membrane composition of liver cells. Poly unsaturated fatty acids are more prone to oxidation than saturated fatty acids and mono unsaturated fatty acids and increase susceptibility to oxidative injury by affecting antioxidant defense systems. The moderately higher carbohydrates, amino acids, fatty acids may have thus offered protection to liver cells. Beta-carotene is an organic compound abundant in plants and is the precursor of Vitamin-A. Consuming foods rich in beta-carotene appears to protect the body from free radicals. Vitamin-C has the ability to donate electrons in a wide range of enzymatic and non-enzymatic reactions makes amino acid the main ROS-detoxifying compound in the aqueous phase. Vitamin C, as a powerful antioxidant, may help to fight cancer by protecting healthy cells from free radical damage and inhibiting the proliferation of cancerous cells. Ascorbic acid is one of the most studied and powerful antioxidants. Vitamin E is responsible for the protection of polyunsaturated fatty acids and which in turn protects the membrane qualities, (fluidity, phase separation and lipid domains). The lower level of vitamins such as α-tocopherol (Vitamin-E) and thiamine are more advantageous to the body, in the functions associated with cofactor such as a Catalase, an antioxidant and its deficiency is linked with increased production of reactive oxygen species. Tocopherol and Thiamine were found to be at trace levels in methanol extract of Spinacia oleracea. Along with the vitamins, the mineral contents of MESO may also have helped reduce the elevated levels of ALT, AST and Bilirubin due to CCl₄ intoxication. It was evidenced that mineral aqueous solution containing sodium and potassium were capable of suppressing the expression of proinflammatory cytokines like tumor necrosis factor (TNF-α) and interleukin (IL-6). It was also reported to reduced the raised level of serum creatine, alanine transaminase (ALT) and aspartate amino transferase (AST) levels due to carbon tetrachloride (CCl₄) intoxication. Aminotransferases (AST) are concentrated mainly in the liver, and their leaching
into the circulation implicate that the integrity of the hepatocytes were disturbed \(^{31}\). Generally, bilirubin conjugates with glucoronic acid in the liver and is later excreted through bile. The presence of higher proportion of bilirubin in serum indicates that the process of conjugation is hampered, reflecting loss of hepatic function \(^{32}\).

Glutathione (GSH) is a tripeptide composed of three different amino acids, glutamate, cysteine and glycine that has numerous important functions within cells. A tripeptide glutathione (γ-glutamylcysteinylglycine) is an abundant compound in plant tissues. It has been found virtually in all cell compartments: cytosol, endoplasmic reticulum, vacuole and mitochondria where GSH executes multiple functions. GSH is the main storage form of sulfur, and it acts as a potent detoxifier of xenobiotics through GSH-conjugation, and can serve as a precursor of phytochelatins \(^{25}\). Flavonoids are natural polyphenolic molecules common to most flowering plants. They include flavonols, flavones, flavanones, isoflavones, catechins, anthocyanidins and chalcones \(^{33}\). Although not considered vitamins and flavonoids have a number of nutritional functions have been described as biological response modifiers. Most of them act as antioxidants and some have anti-inflammatory properties The antioxidants may act as free radical scavengers, reducing agents, chelating agents for transition metals, quenchers of singlet oxygen molecules, and activators of antioxidative defense enzyme systems to suppress radical damage in biological systems \(^{34}\).

In this study, hepatotoxin CCl\(_4\) was used to screen the efficiency of hepatoprotective agents of the plant extract. It was observed that, there was significant increase in the levels of ALT, AST and Bilirubin in the CCl\(_4\) treated group. Generally the oxidative stress and cell damages are correlated with increased level of thiobarbituric reactive substances (TBA) and decrease in packed cell volume (PCV) due to destruction of erythrocytes \(^{16}\). The packed cell volume (PCV) and haemoglobin concentration of CCl\(_4\) control group was reportedly decreased significantly (p<0.05), indicating that there might have been possible destruction of erythrocytes by CCl\(_4\). This observation agrees with the report that CCl\(_4\) toxicity can lead to destruction of hepatocytes and erythrocytes \(^{16}\). At cell level metabolism, this xenobiotic chemical CCl\(_4\) is rapidly transformed by cytochrome P450 2E1 into a trichloromethyl radical which is converted into a peroxyl radical (ROO\(^*\)) in the presence of oxygen. Similarly, superoxide radical (SO\(^*\)) and hydroxyl radicals (OH\(^-\)) are also produced as a part of normal metabolic processes. These radicals may interact with cellular macromolecules and initiate the peroxidative degradation of lipid membranes thus oxidative stress it leads to diverse pathological issues \(^{35}\).

However, the elevated levels of ALT, AST and Bilirubin due to CCl\(_4\) intoxication were moderately reduced (p<0.05) with MESO treatment when compared with CCl\(_4\) exposed control rats. Maximum activity was found with 300μgm/ml dose of MESO. The blood parameters such as erythrocytes, white blood cells and packed cell volumes were also decreased (p<0.05) significantly. The lowered blood parameters were improved to near normal levels with 300μgm/ml dose of MESO. This may be due to improved levels of SOD, GSH, Catalase enzymes and phytochemicals that are present already in the plant part as per preliminary screening and these may offer antioxidant activity such as phenolics,

5. CONCLUSION

In this study, male wistar rats were exposed to CCl$_4$ and in the “in vivo” study, a significant hepatic damage was reported due to oxidative stress. As a result there was rise in the liver marker enzyme activities of ALT, AST and Bilirubin in comparison with normal control rats. The blood parameters such as total WBC, RBC, Hb, Packed cell volume and hepatic architecture were proved to be under disturbance. This may be an indication of cellular leakage and loss of functional integrity of hepatocytes cell membrane. The phytochemical analysis revealed the high content of phenolics and flavonoids in Spinacia oleracea; vitamins and minerals also in a considerable quantity; upon exposure to MESO it was observed and recorded that the reversal of hepatotoxic effects and hepatoremediation did occur. Hence based on the preliminary findings on antioxidant and hepatoprotective activities here
reported, it may be concluded that, methanol extract of *Spinacia oleracea* (MESO) possess significant protection against CCl₄-induced hepatotoxicity in the in vivo studies. This study also delivers the scope to continue study, identify and characterize the active principle(s) and the mechanism involved in the field of Hepatoprotection and Chemoprevention of Hepatotoxicity offered by the antioxidants fraternity of *Spinacia oleracea*.
